

2_Indentations_Variables_Multiline statements

In programming like C, C++ and Java, we use {} brackets to represent a group of code or module

But in **Python indentation** (4 spaces or 1 tab) represents a group of logic.

```
for i in range(10):  
    print(i)
```

if any issues in the code indentations then Error: unindent doesn't match any outer indentation level

```
if True:  
    print("Learning python is easy")  
    a="Data Analytics"  
    print(a)
```

to execute multiple line statements in one line

```
if True: print("Learning python is easy"); a="Data Analytics"; print(a)
```

Multiline statement

Writing same statement in multiple lines instead of single line just like SQL query columns in select query

give \ at the end of each line to consider as one statement or Keep everything in between (and).

```
Hanu= 1 + 2 +  
3 + 4 +  
5 + 6  
Hanu = ( 1 + 2 +  
3 + 4 +  
5 + 6 )  
print(Hanu)
```

Variable

A variable is a named storage location that stores data or values.

variables are used to represent and manipulate data in a program

when you create a variable, you are essentially assigning a name to particular value or data type

a = 10

b = 20

c = 30

the above can be represented by below

a=10; b=20; c=30

a, b, c = 10, 20, 30

age=25

print("My age is ", age, "years old")

print(id(a))

returns the storage **location** where 25 is stored
